

Reconstruction with a 384-sample delay

Imported multitone input, freshly rerun | THR2 = 4096 | Ns = 1024, Ny = 1536

What the spectral mask removes

Interior frame m = 4 | THR2 = 10¹¹ in raw magnitude-squared units | DC remains protected

Higher thresholds change the reconstructed signal

Same input and coefficients | Upper plot aligns output by $D = 384$ | Lower plot includes the full emitted stream

Threshold sweep: suppression versus reconstruction error

11 fresh C++ runs on the same 1024-sample input | Metrics cover all 9 frames or all 1536 output samples

Frame-by-frame spectrum and suppression

Same multitone run, THR2 = 10^11 | Frames 0 and 8 contain zero-padded input boundaries

Frozen window coefficients and 50% overlap

Actual window_gw.memh table | Periodic square-root Hann, F = 15 | FFT length 256, hop 128

Impulse response confirms the sample-domain delay

Fresh impulse reference run | THR2 = 0 | No spectral suppression

Reference-model simulation. Sample codes are not volts. No electrical-energy measurement.
